

Machine-Level Programming IV: Data

Today

Arrays

-  One-dimensional
-  Multi-dimensional (nested)
-  Multi-level

Structures

-  Allocation
-  Access
-  Alignment

Array Allocation

Basic Principle

T $A[L]$;

Array of data type T and length L

Contiguously allocated region of $L * \text{sizeof}(T)$ bytes in memory

Array Access

Basic Principle

T **A**[L] ;

Array of data type T and length L

Identifier **A** can be used as a pointer to array element 0: Type T^*

Reference	Type	Value
<code>val[4]</code>	<code>int</code>	3
<code>val</code>	<code>int *</code>	x
<code>val+1</code>	<code>int *</code>	$x + 4$
<code>&val[2]</code>	<code>int *</code>	$x + 8$
<code>val[5]</code>	<code>int</code>	??
<code>*(val+1)</code>	<code>int</code>	5
<code>val + i</code>	<code>int *</code>	$x + 4 i$

Array Example

```
#define ZLEN 5
typedef int zip_dig[ZLEN];

zip_dig cmu = { 1, 5, 2, 1, 3 };
zip_dig mit = { 0, 2, 1, 3, 9 };
zip_dig ucb = { 9, 4, 7, 2, 0 };
```

- Declaration “`zip_dig cmu`” equivalent to “`int cmu[5]`”
- Example arrays were allocated in successive 20 byte blocks
 - Not guaranteed to happen in general

Array Accessing Example

zip_dig cmu;

```
int get_digit
(zip_dig z, int digit)
{
    return z[digit];
}
```

X86-64

```
# %rdi = z
# %rsi = digit
movl (%rdi,%rsi,4), %eax # z[digit]
```

- Register `%rdi` contains starting address of array
- Register `%rsi` contains array index
- Desired digit at `%rdi + 4*%rsi`
- Use memory reference `(%rdi,%rsi,4)`

Array Loop Example

```
void zincr(zip_dig z) {  
    size_t i;  
    for (i = 0; i < ZLEN; i++)  
        z[i]++;  
}
```

```
# %rdi = z  
movl    $0, %eax           # i = 0  
jmp     .L3                # goto middle  
.L4:                        # loop:  
    addl    $1, (%rdi,%rax,4) # z[i]++  
    addq    $1, %rax        # i++  
.L3:                        # middle  
    cmpq    $4, %rax        # i:4  
    jbe     .L4             # if <=, goto loop  
ret
```

Multidimensional (Nested) Arrays

Declaration

$T \ A[R][C];$

2D array of data type T

R rows, C columns

Type T element requires K bytes

Array Size

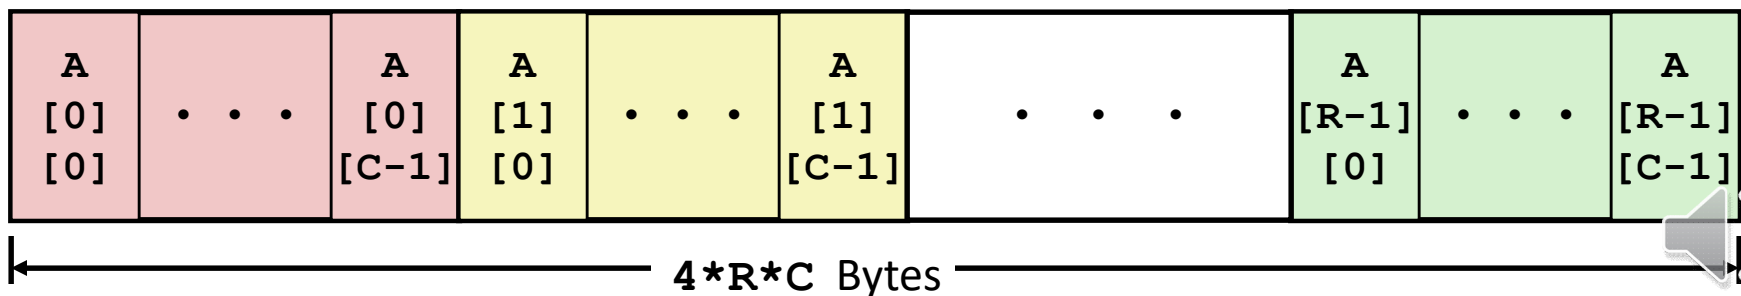

$R * C * K$ bytes

Arrangement

Row-Major Ordering

`int A[R][C];`

Nested Array Example

```
#define PCOUNT 4
zip_dig pgh[PCOUNT] =
    {{1, 5, 2, 0, 6},
     {1, 5, 2, 1, 3 },
     {1, 5, 2, 1, 7 },
     {1, 5, 2, 2, 1 }};
```

🌀 “zip_dig pgh[4]” equivalent to “int pgh[4][5]”

🌀 Variable **pgh**: array of 4 elements, allocated contiguously

🌀 Each element is an array of 5 **int**’s, allocated contiguously

🌀 “Row-Major” ordering of all elements in memory

Nested Array Row Access

Row Vectors

- $A[i]$ is array of C elements
- Each element of type T requires K bytes
- Starting address $A + i * (C * K)$

```
int A[R][C];
```

Nested Array Row Access Code

```
int *get_pgh_zip(int index)
{
    return pgh[index];
}
```

```
# %rdi = index
leaq (%rdi,%rdi,4),%rax # 5 * index
leaq pgh(,%rax,4),%rax  # pgh + (20 * index)
```

Row Vector

- `pgh[index]` is array of 5 `int`'s
- Starting address `pgh+20*index`

Machine Code

- Computes and returns address
- Compute as `pgh + 4*(index+4*index)`

Nested Array Element Access

Array Elements

- $A[i][j]$ is element of type T , which requires K bytes
- Address $A + i * (C * K) + j * K = A + (i * C + j) * K$

```
int A[R][C];
```

Nested Array Element Access Code

```
int get_pgh_digit
(int index, int dig)
{
    return pgh[index][dig];
}
```

```
leaq    (%rdi,%rdi,4), %rax    # 5*index
addl    %rax, %rsi             # 5*index+dig
movl    pgh(,%rsi,4), %eax     # M[pgh + 4*(5*index+dig)]
```

🌀 Array Elements

- 🌀 `pgh[index][dig]` is `int`
- 🌀 Address: `pgh + 20*index + 4*dig`
 - 🌀 $= \text{pgh} + 4*(5*\text{index} + \text{dig})$

Multi-Level Array Example

```
zip_dig cmu = { 1, 5, 2, 1, 3 };  
zip_dig mit = { 0, 2, 1, 3, 9 };  
zip_dig ucb = { 9, 4, 7, 2, 0 };
```

```
#define UCOUNT 3  
int *univ[UCOUNT] = {mit, cmu, ucb};
```

- Variable `univ` denotes array of 3 elements
- Each element is a pointer
 - 8 bytes
- Each pointer points to array of `int`'s

Element Access in Multi-Level Array

```
int get_univ_digit
(size_t index, size_t digit)
{
    return univ[index][digit];
}
```

```
salq    $2, %rsi          # 4*digit
addq    univ(,%rdi,8), %rsi # p = univ[index] + 4*digit
movl    (%rsi), %eax       # return *p
ret
```

Computation

- Element access **Mem[Mem[univ+8*index]+4*digit]**
- Must do two memory reads
 - First get pointer to row array
 - Then access element within array

Array Element Accesses

Nested array

```
int get_pgh_digit
(size_t index, size_t digit)
{
    return pgh[index][digit];
}
```

Multi-level array

```
int get_univ_digit
(size_t index, size_t digit)
{
    return univ[index][digit];
}
```

Accesses looks similar in C, but address computations very different:

$\text{Mem}[\text{pgh} + 20 * \text{index} + 4 * \text{digit}]$ $\text{Mem}[\text{Mem}[\text{univ} + 8 * \text{index}] + 4 * \text{digit}]$

N X N Matrix Code

Fixed dimensions

- Know value of N at compile time

```
#define N 16
typedef int fix_matrix[N][N];
/* Get element a[i][j] */
int fix_ele(fix_matrix a,
            size_t i, size_t j)
{
    return a[i][j];
}
```

Variable dimensions, explicit indexing

- Traditional way to implement dynamic arrays

```
#define IDX(n, i, j) ((i)*(n)+(j))
/* Get element a[i][j] */
int vec_ele(size_t n, int *a,
            size_t i, size_t j)
{
    return a[IDX(n,i,j)];
}
```

Variable dimensions, implicit indexing

- Now supported by gcc

```
/* Get element a[i][j] */
int var_ele(size_t n, int a[n][n],
            size_t i, size_t j) {
    return a[i][j];
}
```

16 X 16 Matrix Access

■ Array Elements

- Address $A + i * (C * K) + j * K$
- $C = 16, K = 4$

```
/* Get element a[i][j] */  
int fix_ele(fix_matrix a, size_t i, size_t j) {  
    return a[i][j];  
}
```

```
# a in %rdi, i in %rsi, j in %rdx  
salq    $6, %rsi           # 64*i  
addq    %rsi, %rdi         # a + 64*i  
movl    (%rdi,%rdx,4), %eax # M[a + 64*i + 4*j]  
ret
```

n X n Matrix Access

■ Array Elements

- Address $A + i * (C * K) + j * K$
- $C = n, K = 4$
- Must perform integer multiplication

```
/* Get element a[i][j] */  
int var_ele(size_t n, int a[n][n], size_t i, size_t j)  
{  
    return a[i][j];  
}
```

```
# n in %rdi, a in %rsi, i in %rdx, j in %rcx  
imulq    %rdx, %rdi          # n*i  
leaq     (%rsi,%rdi,4), %rax  # a + 4*n*i  
movl     (%rax,%rcx,4), %eax  # a + 4*n*i + 4*j  
ret
```

Today

Arrays

-  One-dimensional
-  Multi-dimensional (nested)
-  Multi-level

Structures

-  Allocation
-  Access
-  Alignment

Structure Representation

```
struct rec {  
    int a[4];  
    size_t i;  
    struct rec *next;  
};
```

- **Structure represented as block of memory**
 - Big enough to hold all of the fields
- **Fields ordered according to declaration**
 - Even if another ordering could yield a more compact representation
- **Compiler determines overall size + positions of fields**
 - Machine-level program has no understanding of the structures in the source code

Generating Pointer to Structure Member

```
struct rec {  
    int a[4];  
    size_t i;  
    struct rec *next;  
};
```

Generating Pointer to Array Element

- Offset of each structure member determined at compile time
- Compute as $r + 4 \cdot idx$

```
int *get_ap  
(struct rec *r, size_t idx)  
{  
    return &r->a[idx];  
}
```

```
# r in %rdi, idx in %rsi  
leaq (%rdi,%rsi,4), %rax  
ret
```

Following Linked List

C Code

```
void set_val
(struct rec *r, int val)
{
    while (r) {
        int i = r->i;
        r->a[i] = val;
        r = r->next;
    }
}
```

```
struct rec {
    int a[4];
    int i;
    struct rec *next;
};
```

Element i

Register	Value
%rdi	r
%rsi	val

```
.L11:                                # loop:
    movslq    16(%rdi), %rax          # i = M[r+16]
    movl      %esi, (%rdi,%rax,4)     # M[r+4*i] = val
    movq      24(%rdi), %rdi          # r = M[r+24]
    testq     %rdi, %rdi              # Test r
    jne       .L11                    # if !=0 goto loop
```

Structures & Alignment

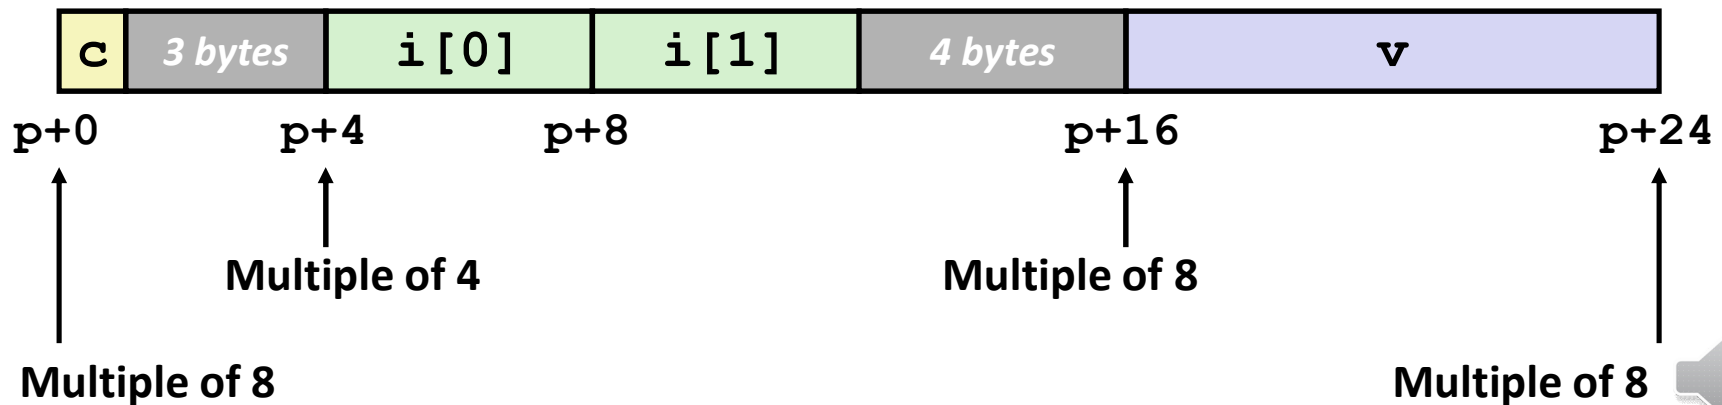

Unaligned Data

```
struct S1 {  
    char c;  
    int i[2];  
    double v;  
} *p;
```

Aligned Data

- Primitive data type requires K bytes
- Address must be multiple of K

Alignment Principles

🌀 Aligned Data

- 🌀 Primitive data type requires K bytes
- 🌀 Address must be multiple of K
- 🌀 Required on some machines; advised on x86-64

🌀 Motivation for Aligning Data

- 🌀 Memory accessed by (aligned) chunks of 4 or 8 bytes (system dependent)
 - 🌀 Inefficient to load or store datum that spans quad word boundaries
 - 🌀 Virtual memory trickier when datum spans 2 pages

🌀 Compiler

- 🌀 Inserts gaps in structure to ensure correct alignment of fields

Specific Cases of Alignment (x86-64)

- 1 byte: **char**, ...

- no restrictions on address

- 2 bytes: **short**, ...

- lowest 1 bit of address must be 0_2

- 4 bytes: **int**, **float**, ...

- lowest 2 bits of address must be 00_2

- 8 bytes: **double**, **long**, **char ***, ...

- lowest 3 bits of address must be 000_2

- 16 bytes: **long double** (GCC on Linux)

- lowest 4 bits of address must be 0000_2

Satisfying Alignment with Structures

Within structure:

- Must satisfy each element's alignment requirement

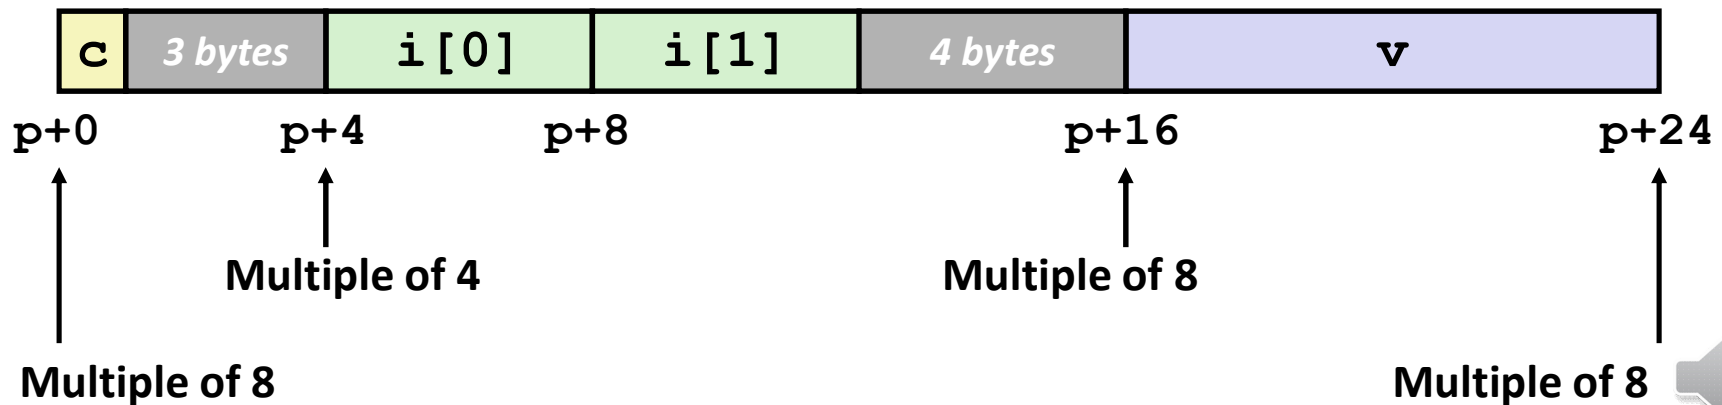

Overall structure placement

- Each structure has alignment requirement K
 - K = Largest alignment of any element
- Initial address & structure length must be multiples of K

```
struct S1 {  
    char c;  
    int i[2];  
    double v;  
} *p;
```

Example:

- $K = 8$, due to **double** element

Meeting Overall Alignment Requirement

- For largest alignment requirement K
- Overall structure must be multiple of K

```
struct S2 {  
    double v;  
    int i[2];  
    char c;  
} *p;
```

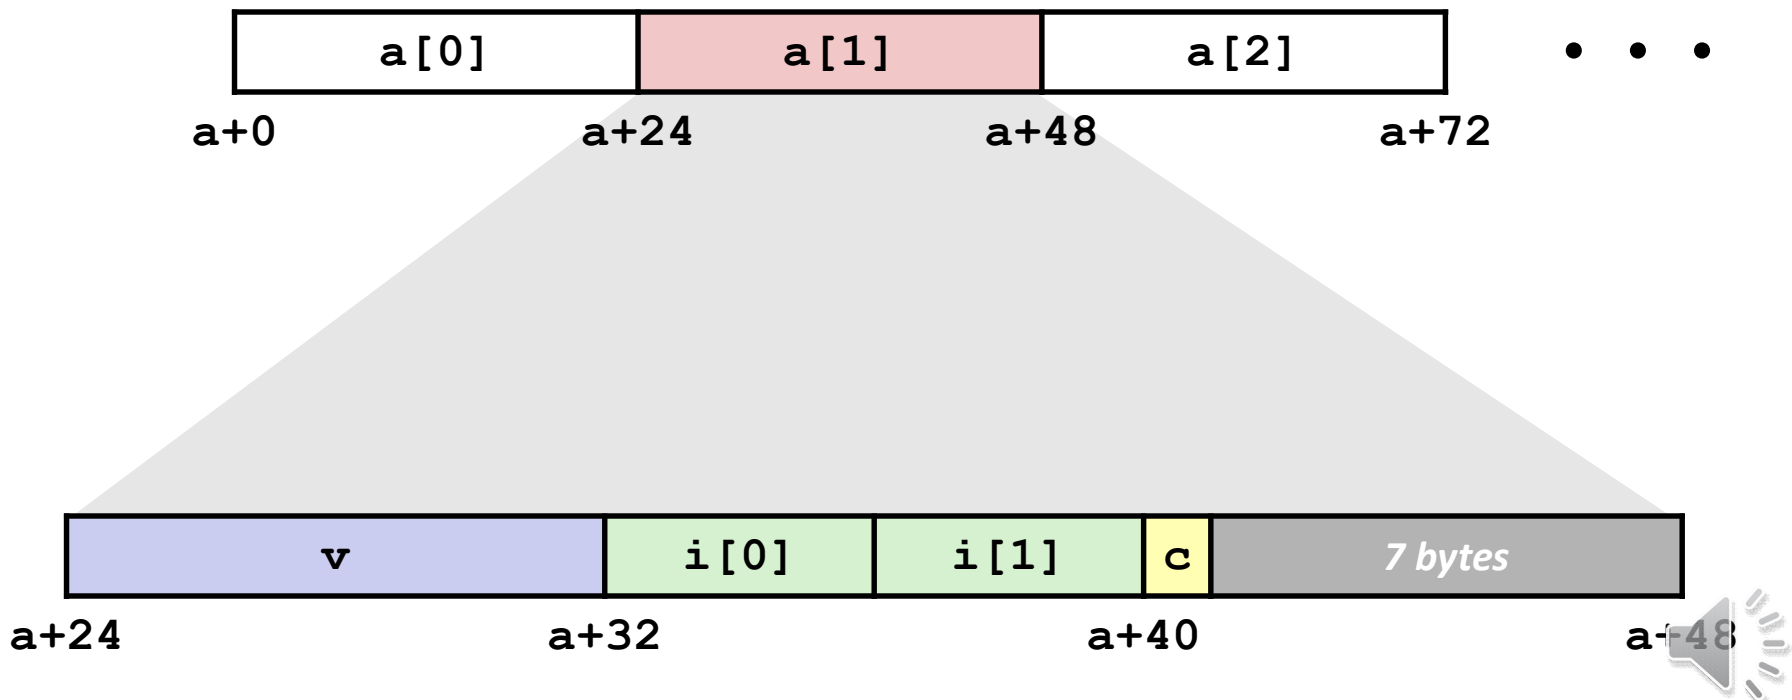

Multiple of $K=8$

Arrays of Structures

- Overall structure length multiple of K
- Satisfy alignment requirement for every element

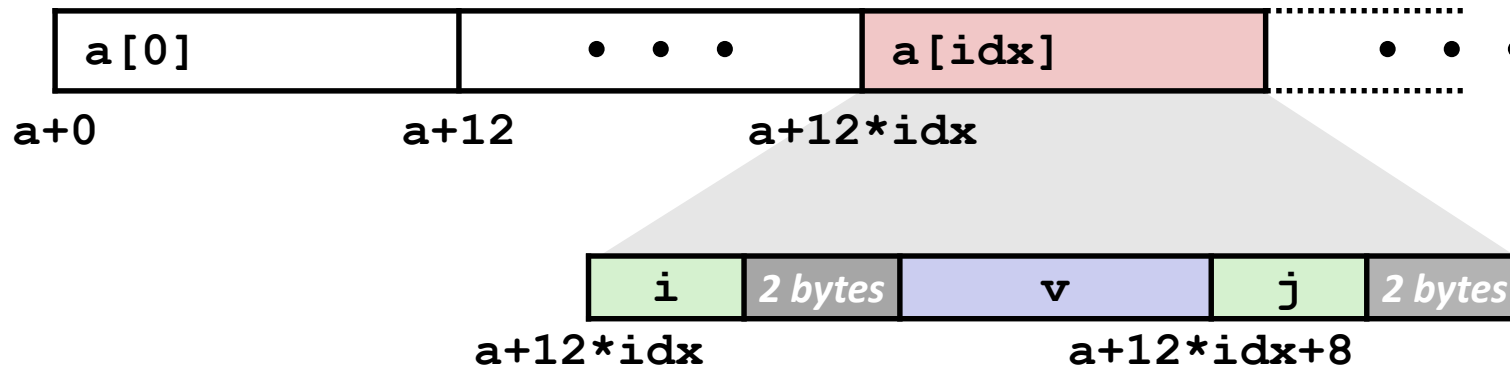

```
struct S2 {  
    double v;  
    int i[2];  
    char c;  
} a[10];
```

Accessing Array Elements

```
struct S3 {  
    short i;  
    float v;  
    short j;  
} a[10];
```

- Compute array offset $12 * \text{idx}$
 - `sizeof(S3)`, including alignment spacers
- Element `j` is at offset 8 within structure
- Assembler gives offset `a+8`
 - Resolved during linking

```
short get_j(int idx)  
{  
    return a[idx].j;  
}
```

```
# %rdi = idx  
leaq (%rdi,%rdi,2),%rax # 3*idx  
movzwl a+8(,%rax,4),%eax
```

Saving Space

Put large data types first

```
struct S4 {  
    char c;  
    int i;  
    char d;  
} *p;
```

```
struct S5 {  
    int i;  
    char c;  
    char d;  
} *p;
```

Effect (K=4)
